Lecture-03 Control

Control

Slides Adapted from cs61a of UC Berkeley

Print and None

(Demo)

None Indicates that Nothing is Returned

The special value **None** represents nothing in Python

A function that does not explicitly return a value will return **None**

Careful: **None** is not displayed by the interpreter as the value of an expression

```
>>> def does_not_return_square(x):  
...     x * x  
...  
>>> does_not_return_square(4)  
>>> sixteen = does_not_return_square(4)  
>>> sixteen + 4
```

No return

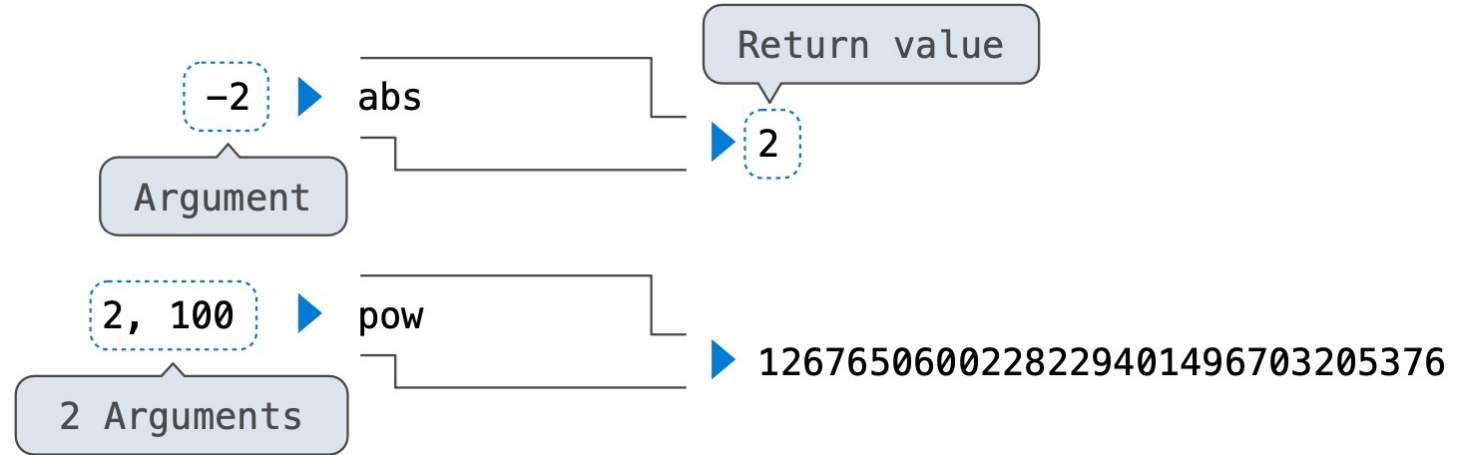

None value is not displayed

The name **sixteen** is now bound to the value **None**

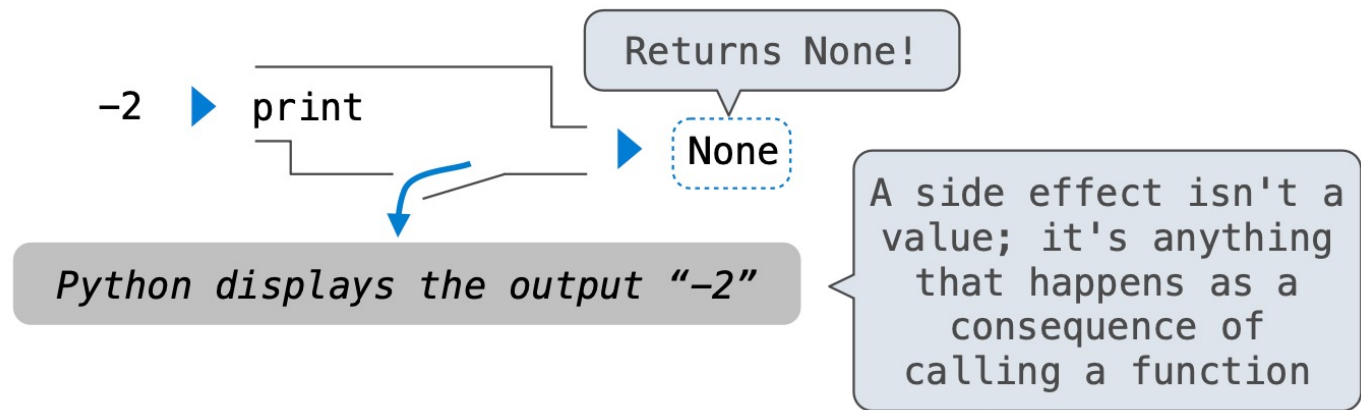

Traceback (most recent call last):
 File "<stdin>", line 1, in <module>
TypeError: unsupported operand type(s) for +: 'NoneType' and 'int'

Pure Functions & Non-Pure Functions

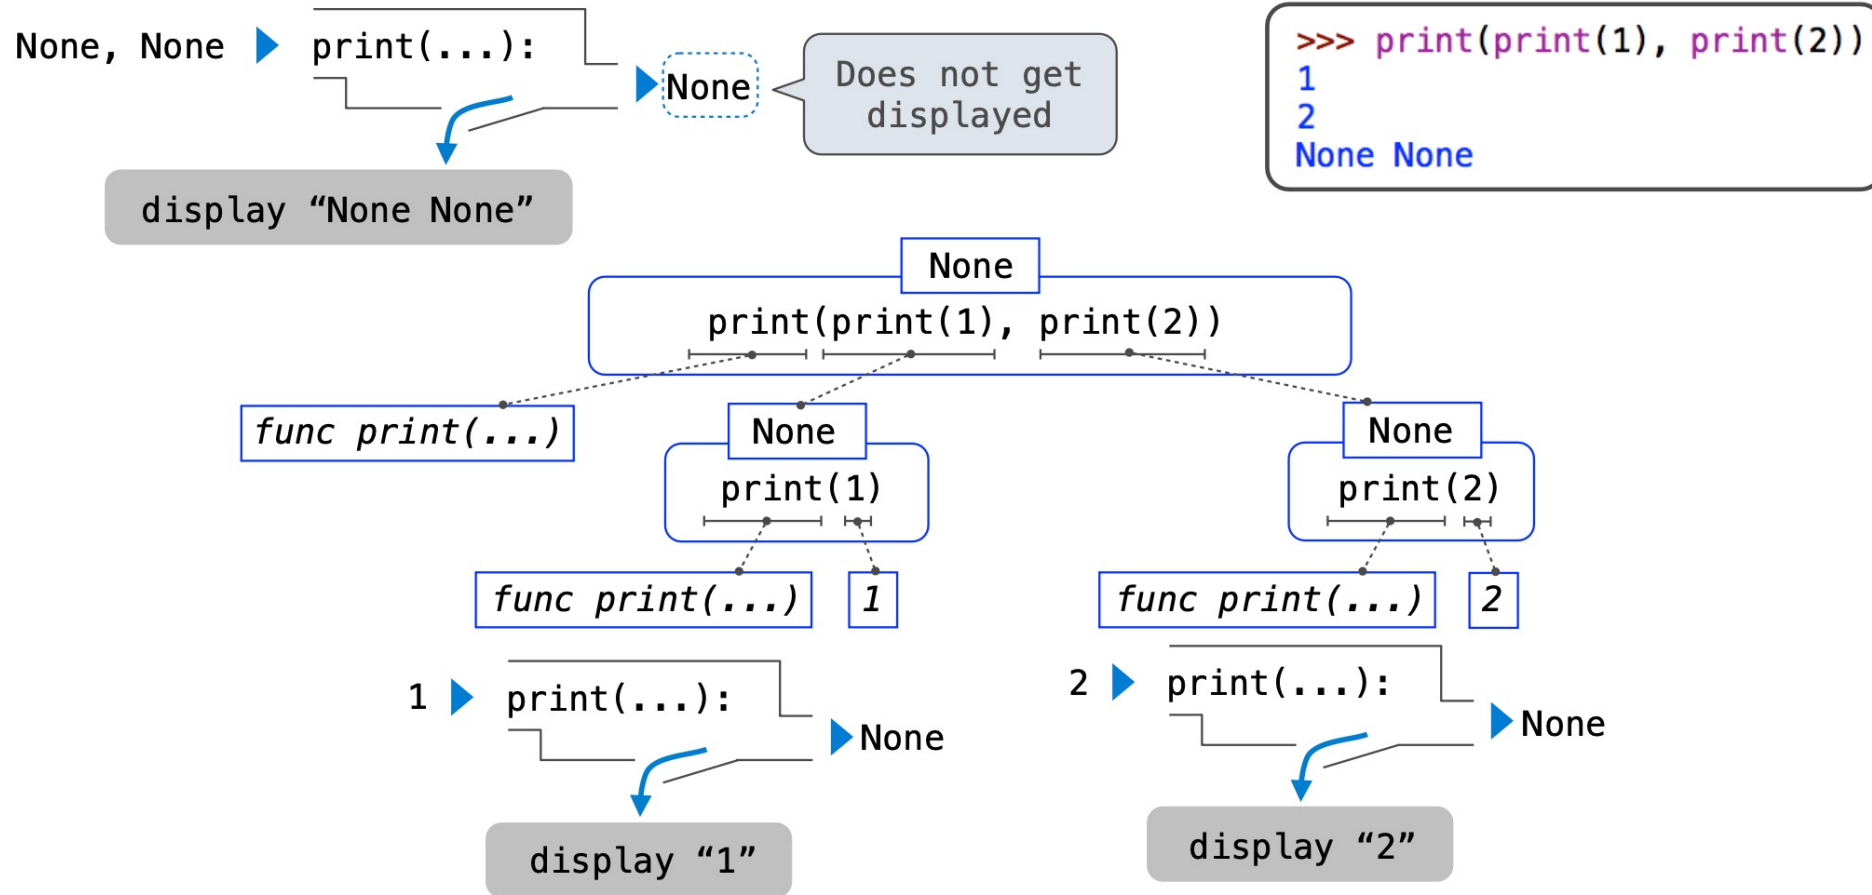

Pure Functions
just return values

Non-Pure Functions
have side effects

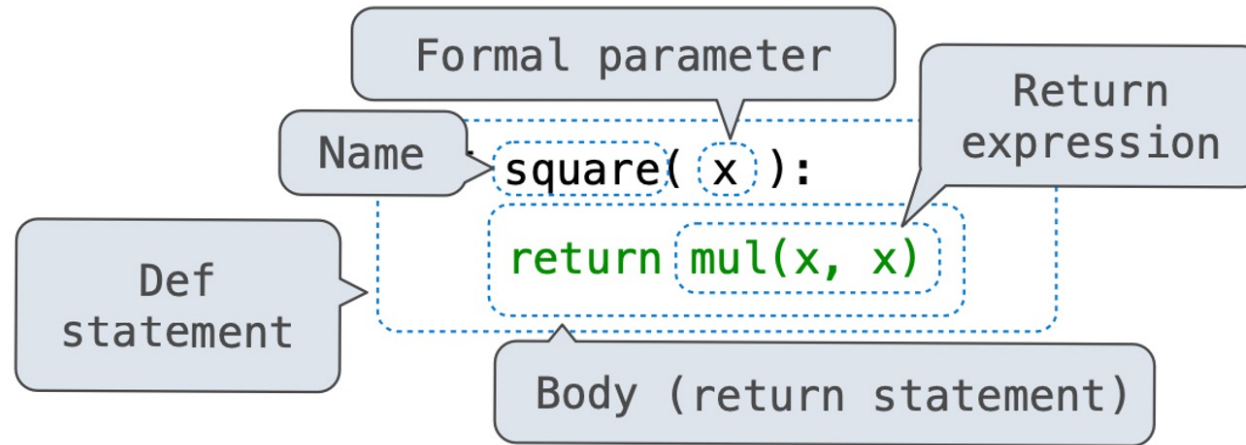

Nested Expressions with Print

Multiple Environments

Life Cycle of a User-Defined Function

Def statement:

What happens?

A new function is created!

Name bound to that function in the current frame

Life Cycle of a User-Defined Function

Call Expression:

What happens?

Operator & operands evaluated

Function (value of operator) called on arguments (values of operands)

Life Cycle of a User-Defined Function

Calling/Applying:

What happens?

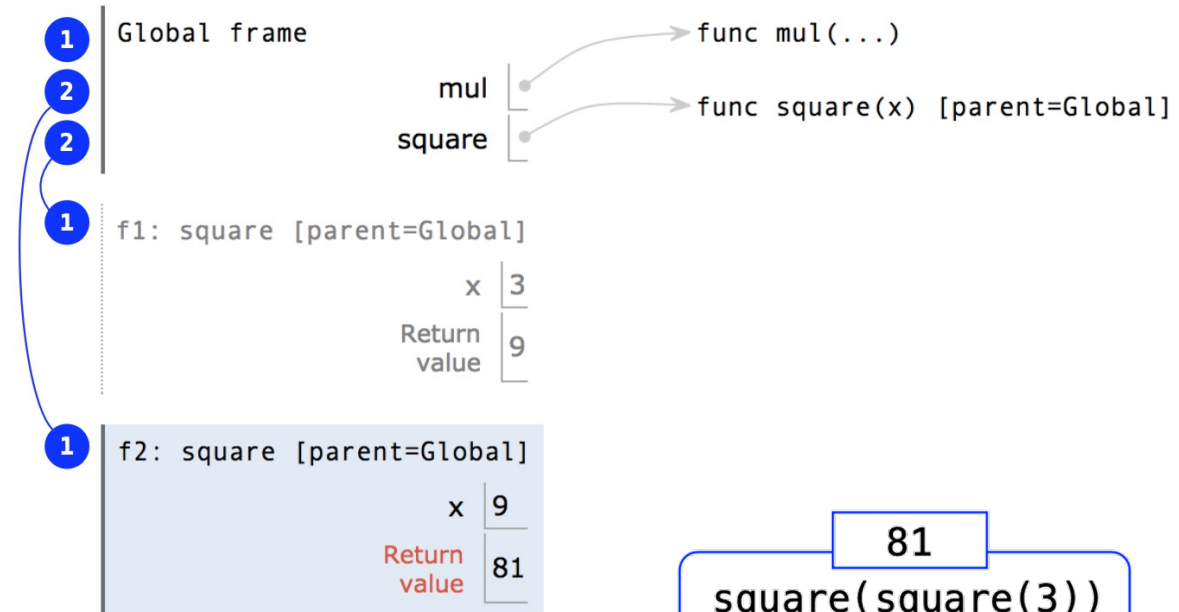

A new frame is created!

Parameters bound to arguments

Body is executed in that new environment

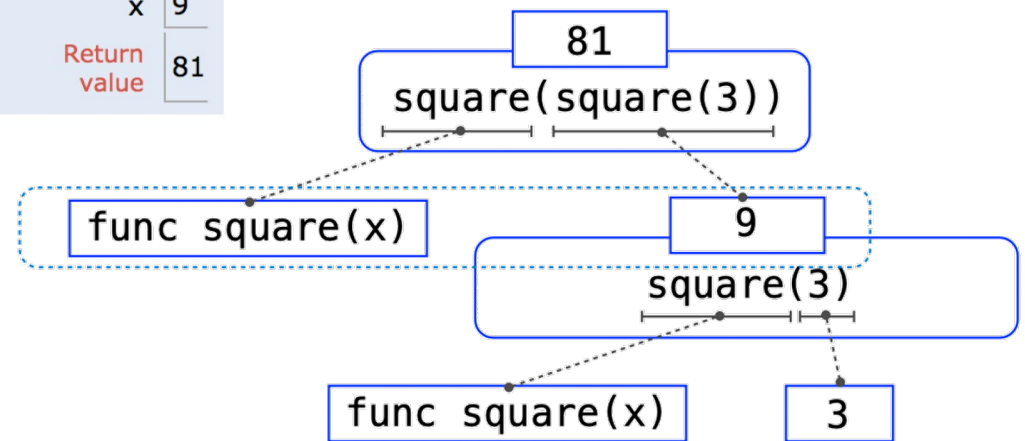

Multiple Environments in One Diagram!

```
1 from operator import mul
2 def square(x):
3     return mul(x, x)
4 square(square(3))
```

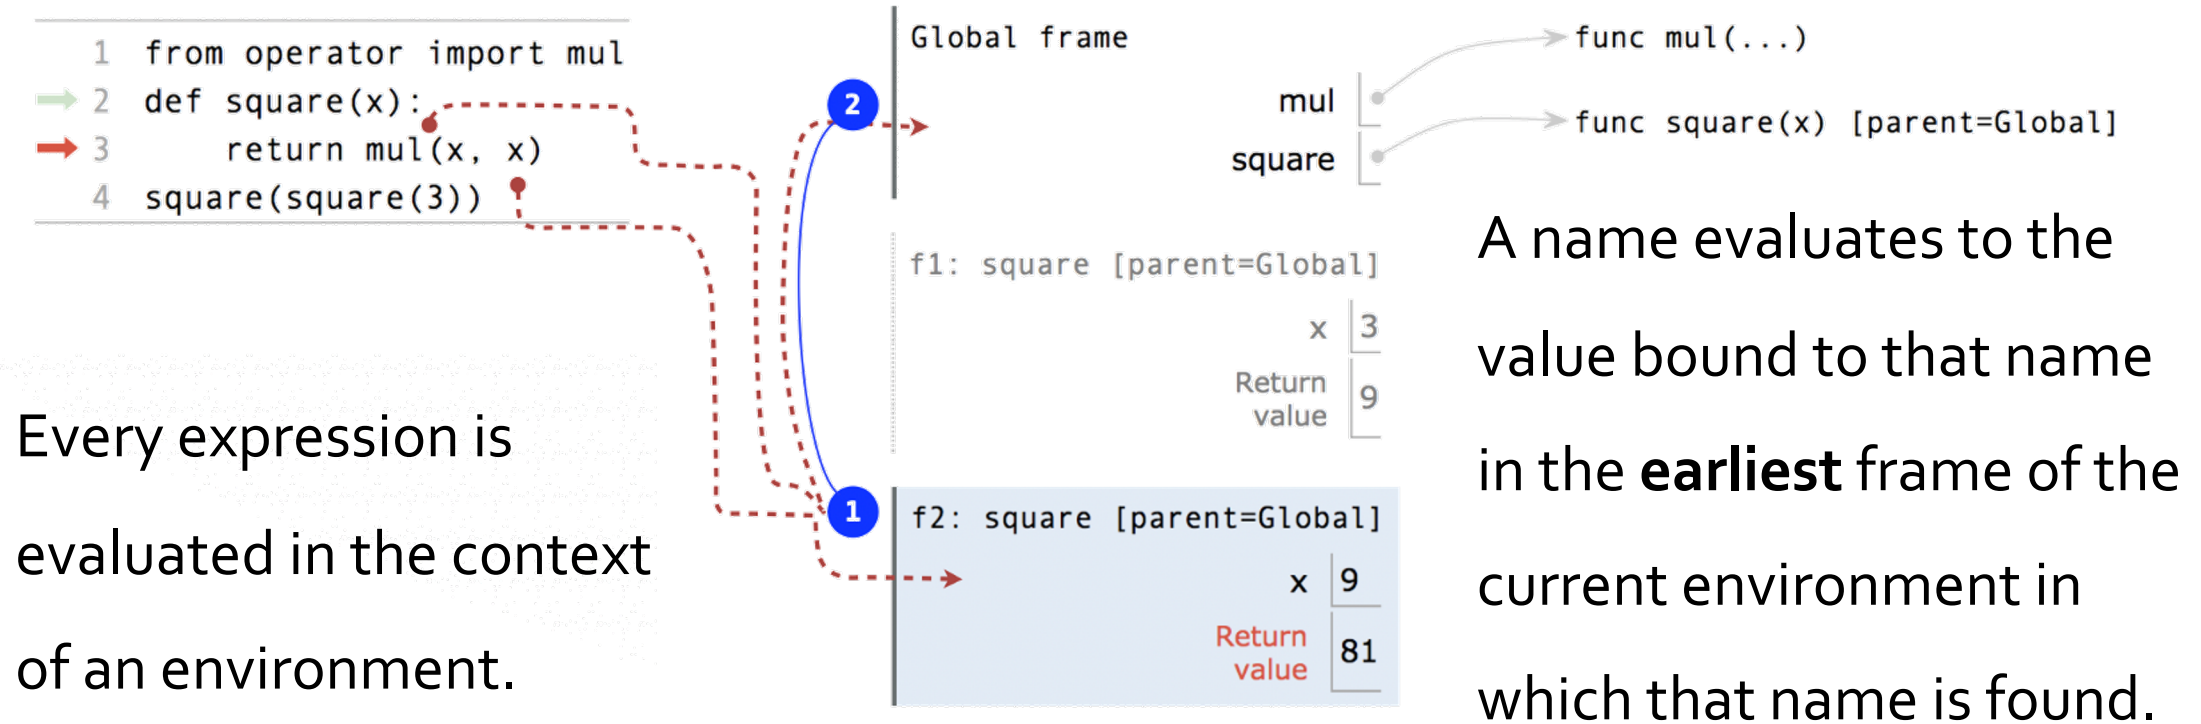

An environment is a sequence of frames.

- The global frame alone
- A local, then the global frame

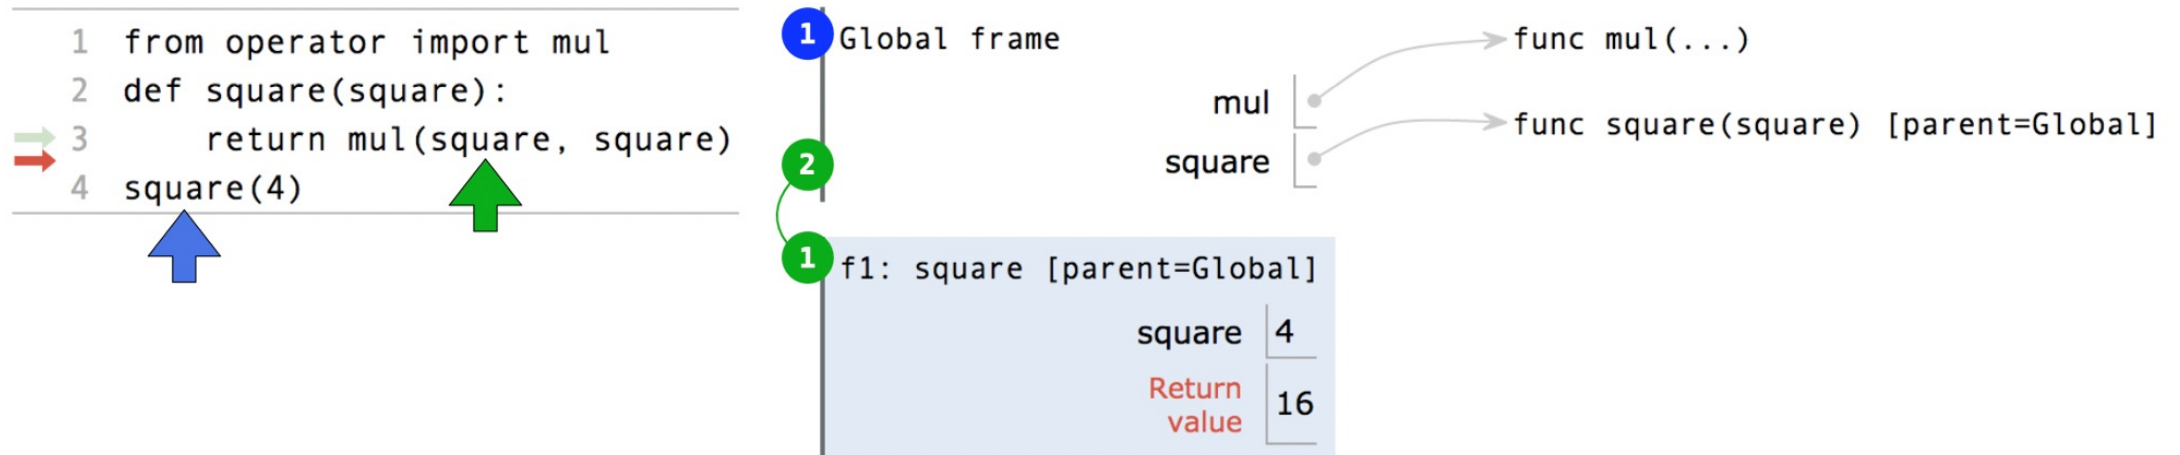

Names Have No Meaning Without Environments

Names Have Different Meanings in Different Environments

A call expression and the body of the function being called are evaluated in different environments.

Miscellaneous Python Features

Miscellaneous Python Features

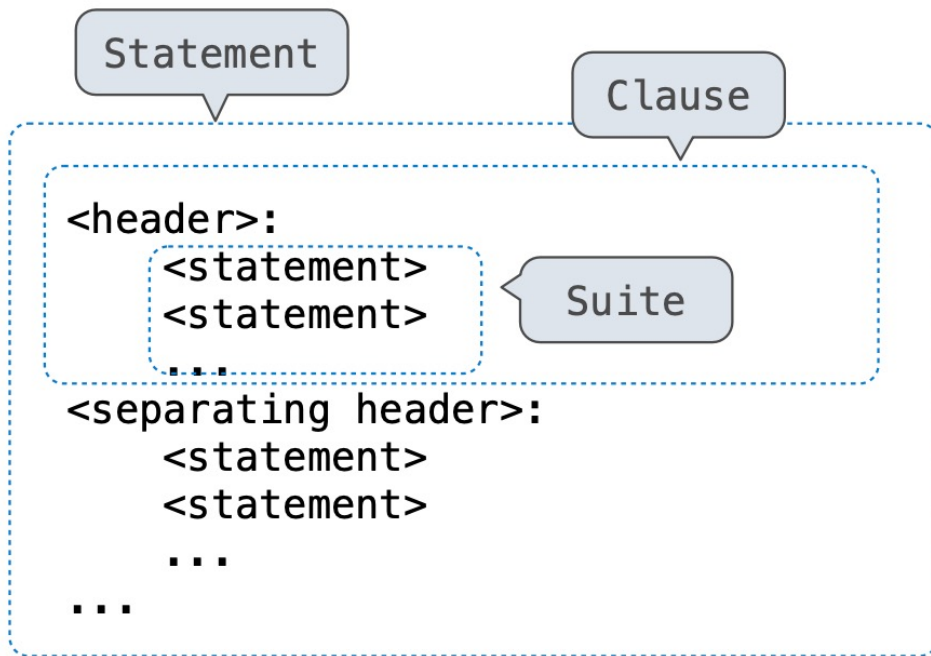

- Division
- Multiple Return Values
- Source Files
- Doctests
- Default Arguments

Conditional Statements

Statements

A **statement** is executed by the interpreter to perform an action

Compound statements:

- The first header determines a statement's type
- The header of a clause "controls" the suite that follows
- def statements are compound statements

Compound Statements

Compound statements:

- A suite is a sequence of statements
- To “execute” a suite means to execute its sequence of statements, in order

Execution Rule for a sequence of statements:

- Execute the first statement
- Unless directed otherwise, execute the rest

Conditional Statements

```
def absolute_value(x):  
    """Return the absolute value of x."""  
    if x < 0:  
        return -x  
    elif x == 0:  
        return 0  
    else:  
        return x
```

1 statement,
3 clauses,
3 headers,
3 suites

Execution Rule for Conditional Statements:

Each clause is considered in order.

1. Evaluate the header's expression.
2. If it is a true value, execute the suite & skip the remaining clauses.

Syntax Tips:

1. Always starts with "if" clause.
2. Zero or more "elif" clauses.
3. Zero or one "else" clause, always at the end.

Boolean Contexts

George Boole

```
def absolute_value(x):  
    """Return the absolute value of x."""  
    if x < 0:  
        return -x  
    elif x == 0:  
        return 0  
    else:  
        return x
```

Two boolean contexts

- False values in Python: False, 0, "", None (more to come)
- True values in Python: Anything else (True)

Iteration

While Statements

George Boole

```
1 i, total = 0, 0
2 while i < 3:
3     i = i + 1
4     total = total + i
```

Global frame

| | | | | |
|-------|--------------|--------------|--------------|---|
| i | 0 | 1 | 2 | 3 |
| total | 0 | 1 | 3 | 6 |

Execution Rule for While Statements:

1. Evaluate the header's expression.
2. If it is a true value, execute the (whole) suite, then return to step 1.

Example: Prime Factorization

Prime Factorization

Each positive integer n has a set of prime factors: primes whose product is n

...

$$8 = 2 * 2 * 2 \quad 9 = 3 * 3$$

$$10 = 2 * 5$$

$$11 = 11$$

$$12 = 2 * 2 * 3$$

...

One approach: Find the smallest prime factor of n , then divide by it

$$858 = 2 * 429 = 2 * 3 * 143 = 2 * 3 * 11 * 13$$

Thanks for Listening
