### Environments

Slides Adapted from cs61a of UC Berkeley

# Environments for Higher-Order Functions

# Environments Enable Higher-Order Functions

Functions are first-class: Functions are values in our programming language

#### **Higher-order function:**

- A function that takes a function as an argument value or
- A function that returns a function as a return value

Environment diagrams describe how higher-order functions work! (Demo)

# Names can be Bound to Functional Arguments

```
Global frame
                                                                 func apply_twice(f, x) [parent=Global]
   def apply_twice(f, x):
        return f(f(x))
                                           apply_twice
                                                                func square(x) [parent=Global]
                                               square
                                                                         Applying a user-defined function:
   def square(x):
                                                                          • Create a new frame
        return x * x
                                                                          • Bind formal parameters
                                                                             (f \& x) to arguments
   result = apply_twice(square, 2)
                                                                          Execute the body:
                                                                             return f(f(x))
                                     Global frame
                                                                         func apply twice(f, x) [parent=Global]
  def apply_twice(f, x):
      return f(f(x))
                                                     apply_twice
                                                                        func square(x) [parent=Global]
                                                         square
  def square(x):
      return x * x
                                      f1: apply_twice [parent=Global]
7 result = apply_twice(square, 2)
                                                             x 2
```

# Environments for Nested Definitions

(Demo)

### Environment Diagrams for Nested Def Statements

```
Nested def
                                             Global frame
                                                                           func make adder(n) [parent=Global]
def make_adder(n):
                                                       make_adder
                                                                           func adder(k) [parent=f1]
    def adder(k):
                                                         add_three
           return k + n
                                             f1: make_adder [parent=G]
      return adder
                                                            adder
add_three = make_adder(3)
                                                            Return
                                                             value
add three(4)
                                             f2: adder [parent=f1]
                                                            Return
                                                             value
```

### Environment Diagrams for Nested Def Statements

- Every user-defined function has a parent frame (often global)
- The parent of a function is the frame in which it was defined
- Every local frame has a parent frame (often global)
- The parent of a frame is the parent of the function called

#### How to Draw an Environment Diagram

#### When a function is defined:

Create a function value: func <name>(<formal parameters>) [parent=<label>] Its parent is the current frame.

```
f1: make_adder func adder(k) [parent=f1]
```

Bind <name> to the function value in the current frame

#### How to Draw an Environment Diagram

#### When a function is called:

- 1. Add a local frame, titled with the <name> of the function being called.
- 2. Copy the parent of the function to the local frame: [parent=<label>]
- 3. Bind the <formal parameters> to the arguments in the local frame.
- 4. Execute the body of the function in the environment that starts with the local frame.

## Local Names

(Demo)

# Local Names are not Visible to Other (Non-Nested) Functions

- An environment is a sequence of frames.
- The environment created by calling a top-level function (no def within def) consists of one local frame, followed by the global frame.

# Lambda Expressions

### Lambda Expressions

```
>>> x = 10

An expression: this one evaluates to a number

>>> square = (x * x)

Also an expression: evaluates to a function

>>> square = lambda x: x * x

Important: No "return" keyword!

A function

with formal parameter x

that returns the value of "x * x"

>>> square(4)

16

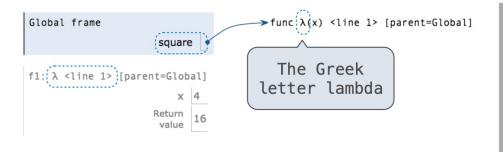

Must be a single expression
```

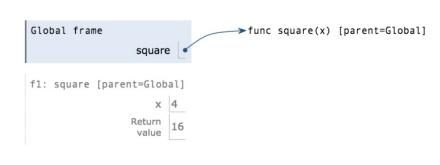

- Lambda expressions are not common in Python, but important in general
- Lambda expressions in Python cannot contain statements at all!

### Lambda Expressions Versus Def Statements

- Both create a function with the same domain, range, and behavior.
- Both bind that function to the name square.
- Only the def statement gives the function an intrinsic name, which shows up in environment diagrams but doesn't affect execution (unless the function is printed).

## **Function Composition**

(Demo)

# The Environment Diagram for Function Composition

```
Global frame
                                                                                                 func square(x) [parent=Global]
    def square(x):
                                                                                 square
         return x * x
                                                                                                func make adder(n) [parent=Global]
                                                                             make adder
                                                                                                func compose1(f, g) [parent=Global]
                                                                               compose1
    def make adder(n):
                                                                                                func adder(k) [parent=f1]
         def adder(k):
                                                               f1: make adder [parent=Global]
              return k + n
                                                                                                 func h(x) [parent=f2]
         return adder
                                                                                  adder
                                                                                  Return
                                                                                  value
    def compose1(f, g):
         def h(x):
                                                               f2: compose1 [parent=Global]
              return f(g(x))
         return h
                                                                                  Return
14 compose1(square, make_adder(2))(3)
                                                               f3: h [parent=f2]
                                                                                     x 3
       Return value of make adder is
           an argument to compose1
                                                                f4: adder [parent=f1]
                                                                                     k 3
```

## Self-Reference

(Demo)

### Returning a Function Using Its Own Name

```
1 def print_sums(n):
2    print(n)
3    def next_sum(k):
→ 4         return print_sums(n+k)
5    return next_sum
6
→ 7 print_sums(1)(3)(5)
```

# Currying

### **Function Currying**

```
def make_adder(n):
    return lambda k: n + k

>>> make_adder(2)(3)
5
>>> add(2, 3)
5
these functions

(Demo)
```

**Curry:** Transform a multi-argument function into a single-argument, higher-order function

# Thanks for Listening
